

# Homogeneous quasimorphisms on the symplectic linear group

Gabi Ben Simon      Dietmar A. Salamon  
ETH-Zürich

11 December 2007

Let  $G$  be a group. A **quasimorphism** on  $G$  is a map  $\rho : G \rightarrow \mathbb{R}$  satisfying

$$|\rho(gh) - \rho(g) - \rho(h)| \leq C$$

for all  $g, h \in G$  and a suitable constant  $C$ . It is called **homogeneous** if  $\rho(g^k) = k\rho(g)$  for every  $g \in G$  and every integer  $k \geq 0$ . Let

$$\mathrm{Sp}(2n) := \{ \Psi \in \mathbb{R}^{2n \times 2n} \mid \Psi J_0 \Psi^T = J_0 \}, \quad J_0 := \begin{pmatrix} 0 & -\mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix},$$

denote the group of symplectic matrices and  $\widetilde{\mathrm{Sp}}(2n)$  its universal cover. Think of an element of  $\widetilde{\mathrm{Sp}}(2n)$  as a homotopy class  $[\Psi]$  (with fixed endpoints) of a smooth path  $\Psi : [0, 1] \rightarrow \mathrm{Sp}(2n)$  satisfying  $\Psi(0) = \mathbb{1}$ .

**Theorem 1.** *There is a unique homogeneous quasimorphism  $\mu$  on  $\widetilde{\mathrm{Sp}}(2n)$  that descends to the determinant homomorphism on  $\mathrm{U}(n)$  in the sense that*

$$\det(X + iY) = \exp(2\pi i \mu([\Psi])), \quad \begin{pmatrix} X & -Y \\ Y & X \end{pmatrix} := \Psi(1),$$

for every  $[\Psi] \in \widetilde{\mathrm{Sp}}(2n)$  with  $\Psi(1) \in \mathrm{Sp}(2n) \cap \mathrm{O}(2n) \cong \mathrm{U}(n)$ .

The quasimorphism of Theorem 1 plays a central role in [2] and this motivated the present note. Two explicit constructions of the quasimorphism can be found in [1] and [4]. The construction in [1] uses the unitary part in a polar decomposition and homogenization. The construction in [4] uses the

eigenvalue decomposition of a symplectic matrix (but does not mention the term *quasimorphism*).

**Lemma 1** *If  $\rho : G \rightarrow \mathbb{R}$  is a homogeneous quasimorphism then  $\rho$  is invariant under conjugation and  $\rho(g^{-1}) = -\rho(g)$  for every  $g \in G$ .*

*Proof of Lemma 1.* Let  $C$  be the constant in the definition of quasimorphism. By homogeneity, we have  $\rho(1) = 0$ . Hence  $|\rho(g^k) + \rho(g^{-k})| \leq C$  for every  $g \in G$  and every integer  $k \geq 0$ . By homogeneity, we obtain  $|\rho(g) + \rho(g^{-1})| \leq C/k$  for every  $k$  and so  $\rho(g^{-1}) = -\rho(g)$ . Hence

$$|\rho(ghg^{-1}) - \rho(h)| = |\rho(ghg^{-1}) - \rho(g) - \rho(h) - \rho(g^{-1})| \leq 2C.$$

Using homogeneity again we obtain  $\rho(ghg^{-1}) = \rho(h)$  for all  $g, h \in G$ .  $\square$

*Proof of Theorem 1.* Let  $\mathcal{P} \subset \text{Sp}(2n)$  denote the set of symmetric positive definite symplectic matrices. This space is contractible and hence there is a natural injection  $\iota : \mathcal{P} \rightarrow \widetilde{\text{Sp}}(2n)$ . Explicitly, the map  $\iota$  assigns to a matrix  $P \in \mathcal{P}$  the unique homotopy class of paths  $\Phi : [0, 1] \rightarrow \mathcal{P}$  with endpoints  $\Phi(0) = \mathbb{1}$  and  $\Phi(1) = P$ .

Let  $\mu : \widetilde{\text{Sp}}(2n) \rightarrow \mathbb{R}$  be a homogeneous quasimorphism that descends to the determinant homomorphism on  $\text{U}(n)$ . It suffices to prove that the restriction of  $\mu$  to  $\iota(\mathcal{P})$  is bounded. (If  $\mu'$  is another quasimorphism satisfying the requirements of Theorem 1 and  $\mu, \mu'$  are bounded on  $\iota(\mathcal{P})$  then, by polar decomposition and the determinant assumption, their difference is bounded and so, by homogeneity, they are equal.) We prove that  $\mu$  vanishes on  $\iota(\mathcal{P})$ . For every unitary matrix  $Q \in \text{U}(n) \subset \text{Sp}(2n)$  and every  $P \in \mathcal{P}$  we have

$$(1) \quad \mu(\iota(QPQ^T)) = \mu(\iota(P)).$$

To see this, choose two paths  $\Phi : [0, 1] \rightarrow \mathcal{P}$  and  $\Psi : [0, 1] \rightarrow \text{U}(n)$  such that  $\Phi(0) = \Psi(0) = \mathbb{1}$  and  $\Phi(1) = P$ ,  $\Psi(1) = Q$ . Then  $\mu([\Phi]) = \mu([\Psi\Phi\Psi^{-1}])$ , by Lemma 1, and so (1) follows from the fact that  $\Psi^{-1} = \Psi^T$ . Now let  $P \in \mathcal{P}$ . Since  $P$  is a symmetric symplectic matrix we have  $PJ_0P = J_0$  and hence

$$\mu(\iota(P)) = \mu(\iota(J_0P^{-1}J_0^{-1})) = \mu(\iota(P^{-1})) = \mu(\iota(P)^{-1}) = -\mu(\iota(P)).$$

Here the second equation follows from (1) and the last from Lemma 1. This shows that  $\mu(\iota(P)) = 0$  for every  $P \in \mathcal{P}$ .  $\square$

**Remark 1.** Lemma 1 is well known to the experts. We included a proof to give a self-contained exposition, and because we didn't find an explicit reference.

**Remark 2.** Related results, obtained with different methods, are contained in [1] and [3]. Our main theorem can in fact be deduced from these results.

**Remark 3.** The determinant homomorphism  $\det : U(n) \rightarrow S^1$  is uniquely determined by the condition that it induces an isomorphism on fundamental groups. Hence it follows from Theorem 1 that the homogeneous quasimorphism  $\mu : \widetilde{\mathrm{Sp}}(2n) \rightarrow \mathbb{R}$  is uniquely determined by the condition that it restricts to an isomorphism of the fundamental group of  $\mathrm{Sp}(2n)$  to the integers.
